## Relativistic Rankine-Hugoniot Equations

A. H. TAUB

*University of Illinois, Urbana, Illinois and Institute for Advanced Study, Princeton University, Princeton, New Jersey\**

Next we suppose that the three-dimensional volume is a shell of thickness  $\epsilon$  enclosing a surface of discontinuity  $\Sigma$  whose three-dimensional normal vector is  $\Lambda_i$ . If we choose our coordinate system so that the discontinuity is at rest, then since

$$\underline{\lambda_\alpha \lambda^\alpha = 1}, \quad \sum_{i=1}^3 \Lambda_i^2 = 1,$$

we have

$$\lambda_i = \Lambda_i \quad \text{and} \quad \underline{\lambda_4 = 0}. \quad \leftarrow$$

Hence Eqs. (7.1) and (7.2) become, as  $\epsilon$  goes to zero,

$$[\rho^0 u^i \Lambda_i] = 0, \quad (7.3)$$

$$[T^{\alpha i} \Lambda_i] = 0, \quad (7.4)$$

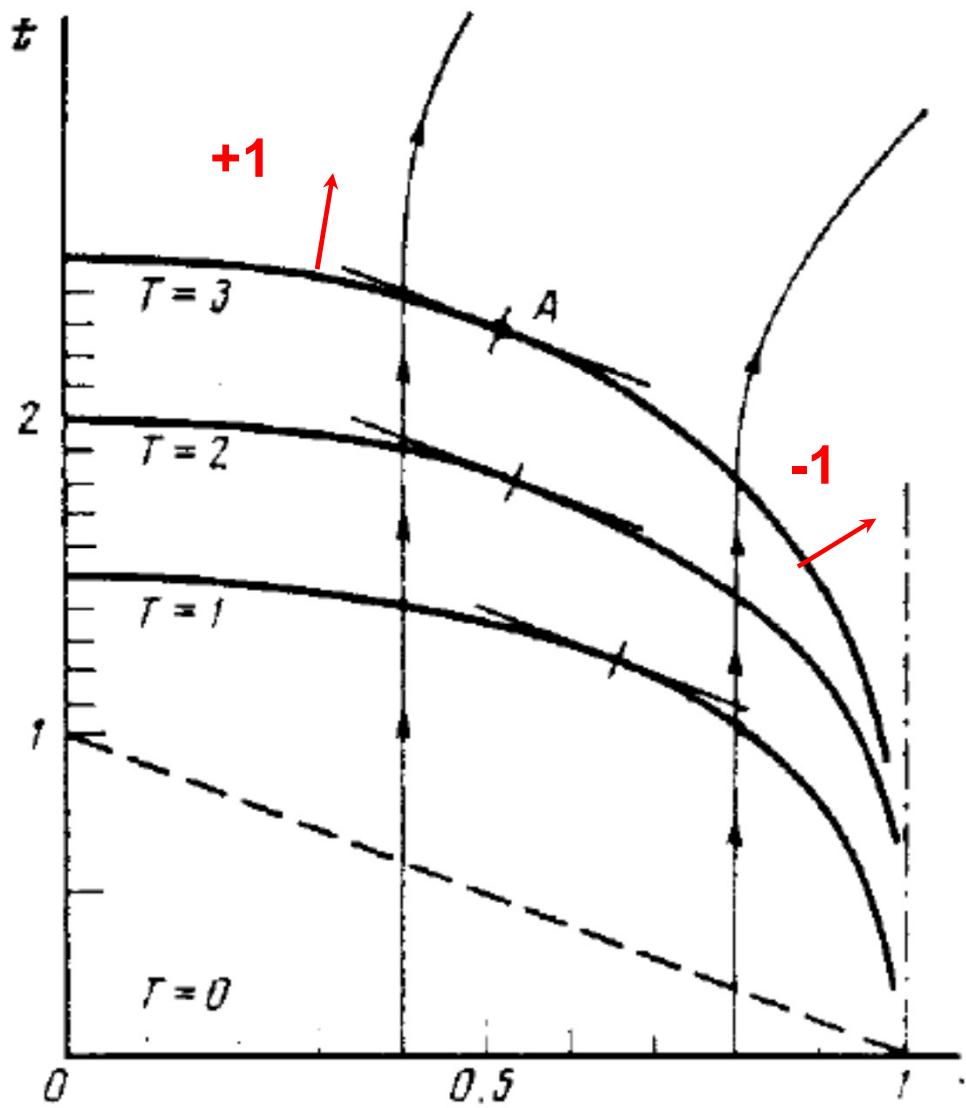

where

$$[f] = f_+ - f_-$$

Csernai, L.P. [NAPLIFE]

Taub assumed that (physically) only slow space-like shocks or discontinuities may occur (with space-like normal,  $\lambda_4=0$ ).

This was then taken as standard, since then (e.g. LL 1954-)<sub>9</sub>

[ L. P. Csernai, Zh. Eksp. Teor. Fiz. 92, 379-386 (1987) & Sov. Phys. JETP 65, 216-220 (1987) ]

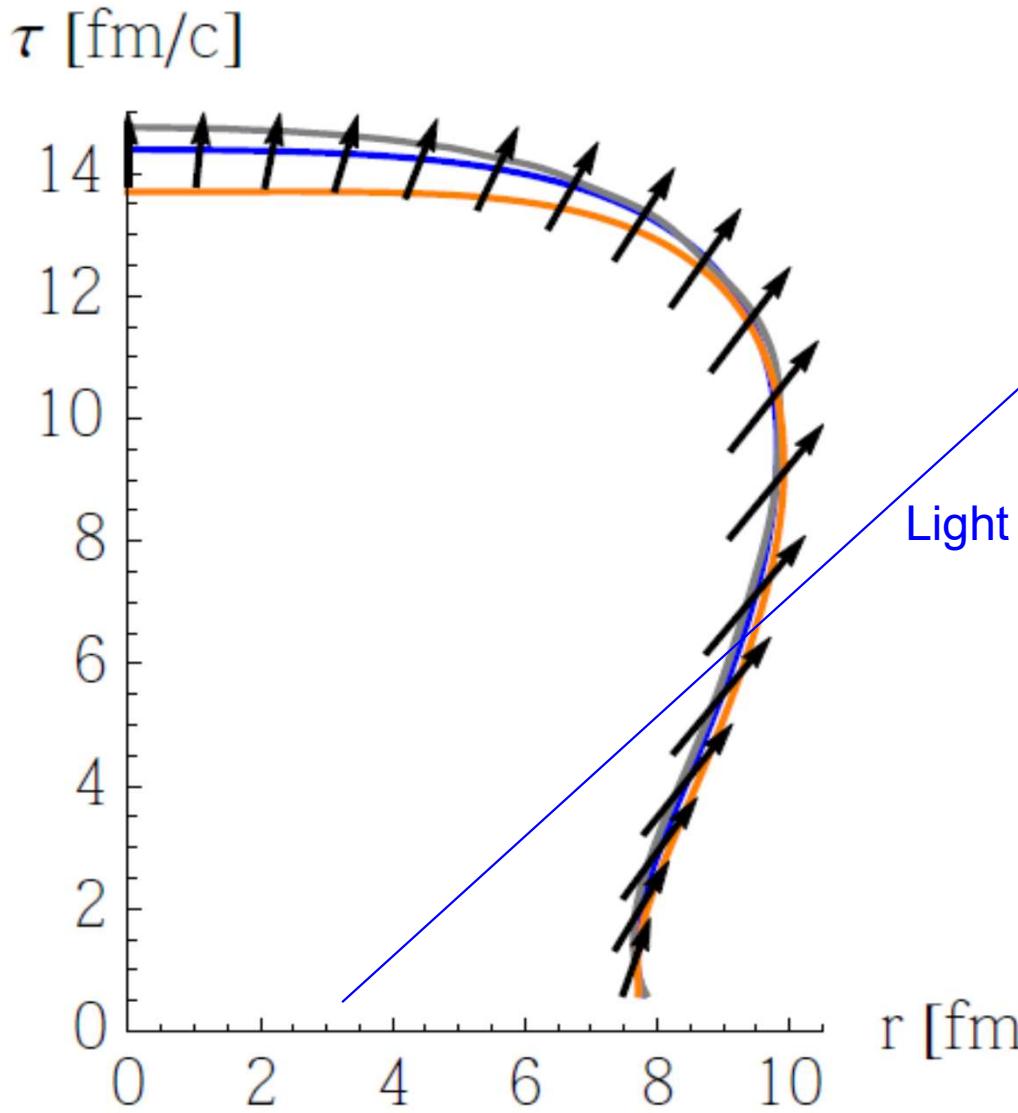

corrected the work of  
[ A. Taub, Phys. Rev. 74, 328 (1948) ]

$$\lambda_a \lambda^a = \pm 1$$

### Abstract

Inertial Confinement Fusion is a promising option to provide massive, clean, and affordable energy for mankind in the future. The present status of research and development is hindered by hydrodynamical instabilities occurring at the intense compression of the target fuel by energetic laser beams. A recent patent combines advances in two fields: Detonations in relativistic fluid dynamics (RFD) and radiative energy deposition by plasmonic nano-shells. The initial compression of the target pellet can be decreased, not to reach the Rayleigh-Taylor or other instabilities, and rapid volume ignition can be achieved by a final and more energetic laser pulse, which can be as short as the penetration time of the light across the pellet. The reflectivity of the target can be made negligible as in the present direct drive and indirect drive experiments, and the absorptivity can be increased by one or two orders of magnitude by plasmonic nano-shells embedded in the target fuel. Thus, higher ignition temperature and radiation dominated dynamics can be achieved with the limited initial compression. Here, we propose that a short final light pulse can heat the target so that most of the interior will reach the ignition temperature simultaneously based on the results of RFD. This makes the development of any kind of instability impossible, which would prevent complete ignition of the target.

# Golden Nano-Shells – Resonant Light Absorption

The absorption coefficient is **linearly** changing with the radius: In the center,  
 $r = 0, \alpha_K = 30 \text{ cm}^{-1}$   
while at the outside edge  $\alpha_K = 8 \text{ cm}^{-1}$ .

The temperature is measured in units of  
 $T_1 = 272 \text{ keV}$ , and  $T_n = n T_1$ .

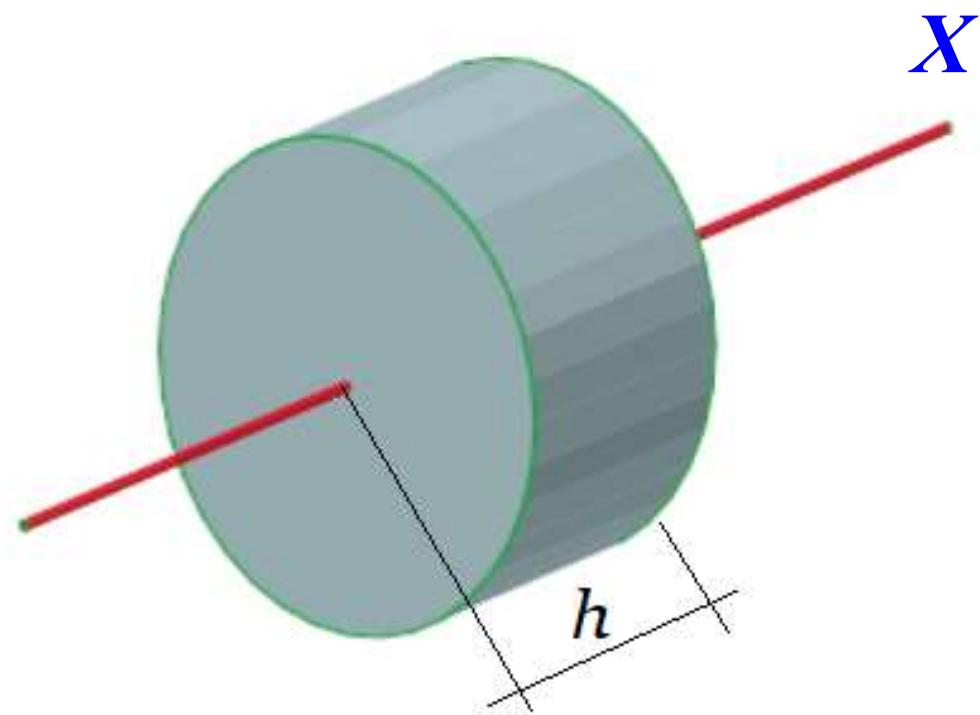

**Simultaneous, volume ignition is up to 0.9 R, so 73% of the fuel target!**

**How can we realize it  
simpler and with less  
expense**

# Thick coin like flat target & Two beams only

Thickness of  
the target is:  $h$

$h$  depends on  
pulse energy,  
ignition energy,  
target mass, ...

Target thickness,  $h$  ( $3.6\mu\text{m}$ - $1\text{mm}$ )  
& radius,  $R$ , ( $150$ - $400\mu\text{m}$ ) were varied.

Csernai, L.P. [NAPLIFE]

Total pulse energy  $1.2\text{kJ}$  (2ns) for 8 beams.  
Shortest (250ps) pulses  $\rightarrow$   $100\text{s MeV}$  ions >  
non-thermal distr. = directed ion acceleration

Typical fusion neutron energies were measured  
& used to extract the target density.

## Experimental test of similar configuration @ ShenGuang-II Up, Shanghai :

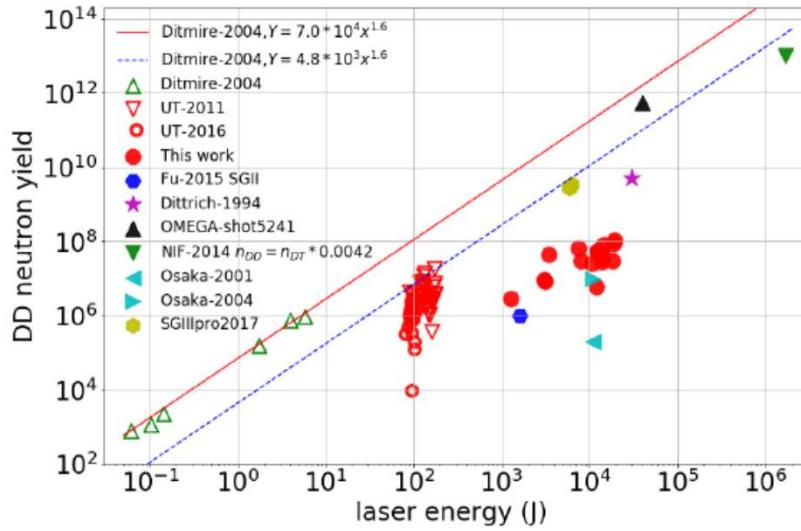

Figure 3: (color online) Fusion yield as function of laser energy. Different experimental results Ditmire-2004[40], UT-2011[20], UT-2016[19], Fu-2015 SGII[45], Dittrich-1994[49] , NIF-2014[48] , Osaka -2001[46], Osaka-2004[47], OMEGA-shot5241[41]and SGIIpro2017[42] are indicated in the inset.

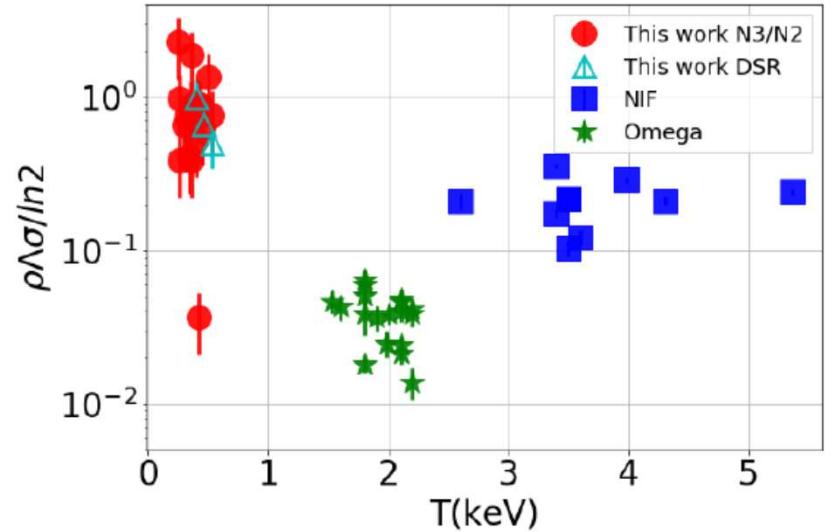

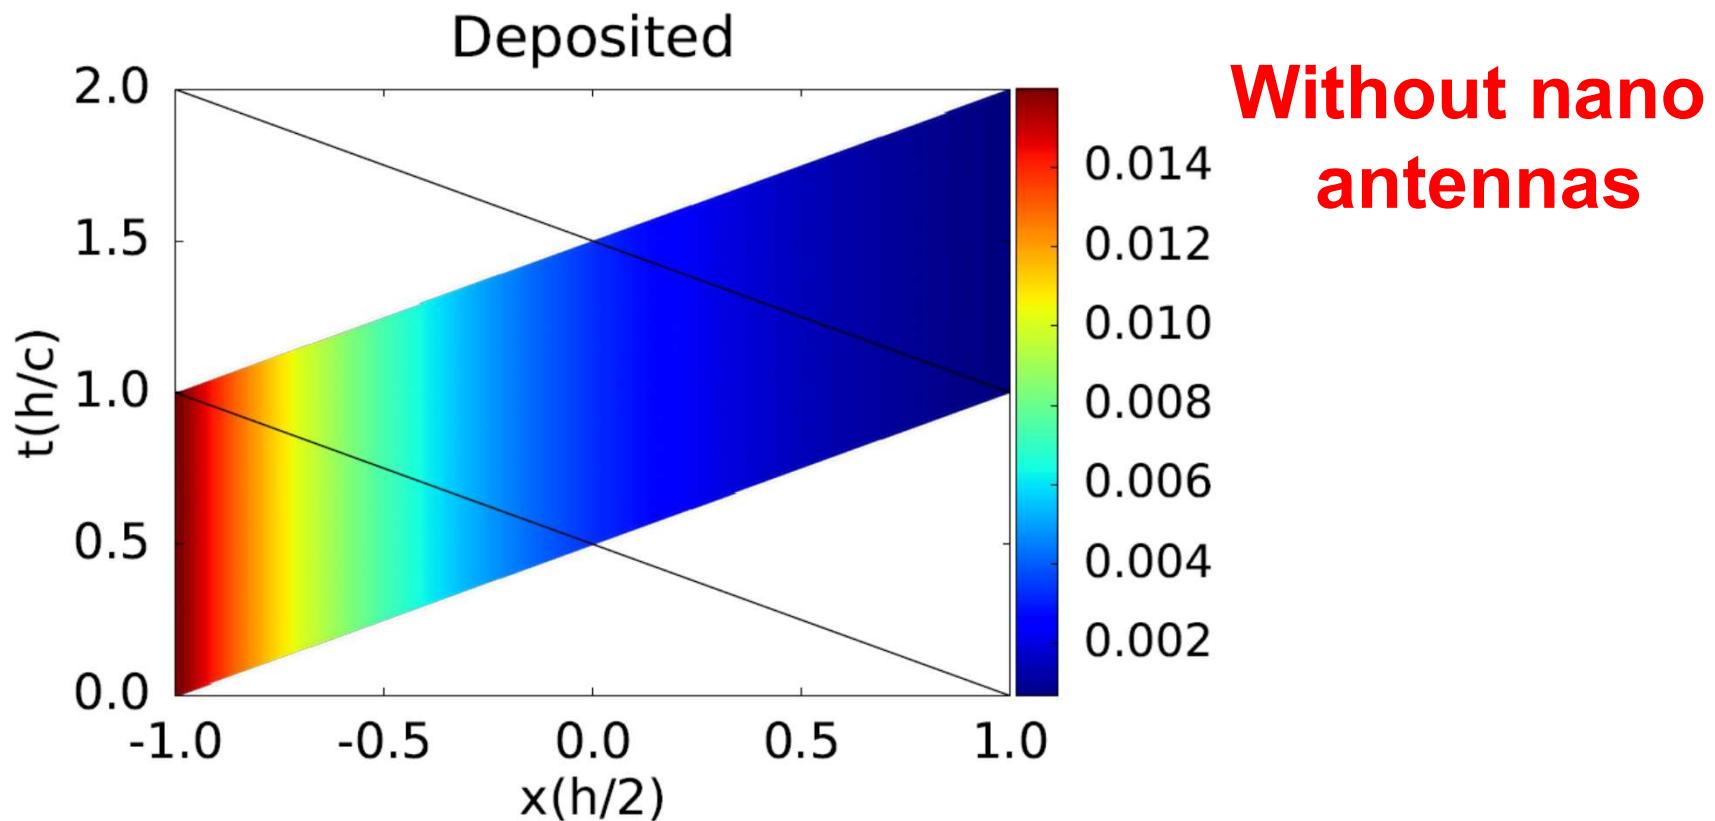

Figure 4: (color online)  $\Lambda\rho\sigma/\ln 2$  obtained from eq.(4) vs  $T$  from eq.(1). Omega and NIF data are derived from the experiments[25], using the Down Scatter Ratio[23, 21]. Our results using the DSR method ( $N_4/N_3$ ) are given by the open triangle symbols in good agreement with the  $N_3/N_2$  ratios.

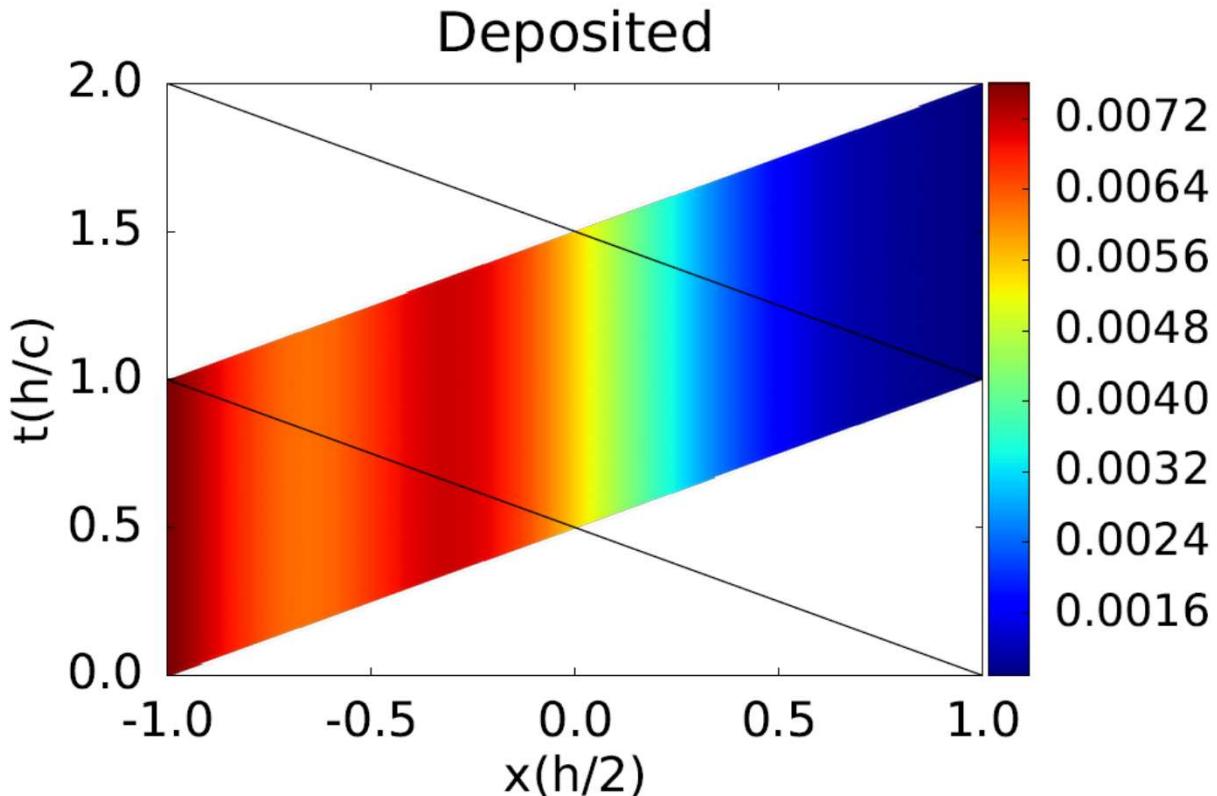

Stimulated by these considerations we decided not to fight non-equilibrium effects but rather enhance them, i.e. study plasmas highly compressed and completely out of equilibrium. A scheme for a colliding

**However,**

- no simultaneous ignition, and**
- no nano-antennas up to now !**

The deposited energy from laser irradiation from one side only. The absorption is constant, this leads to an exponentially decreasing energy deposition, and only a negligibly small energy reaches the opposite end of the target.

**With nano antennas**

The absorptivity is increased towards the center, due to the implanted nano antennas.

The deposited energy from laser irradiation from one side only. The absorption is modified by nano antennas so that the absorptivity is increasing towards the middle, so that the deposited energy is constant up to the middle. Then the absorptivity is decreasing, but hardly any energy is left in the irradiation front. Thus again only a negligibly small energy reaches the opposite end of the target.

Csernai, L.P. [NAPLIFE}

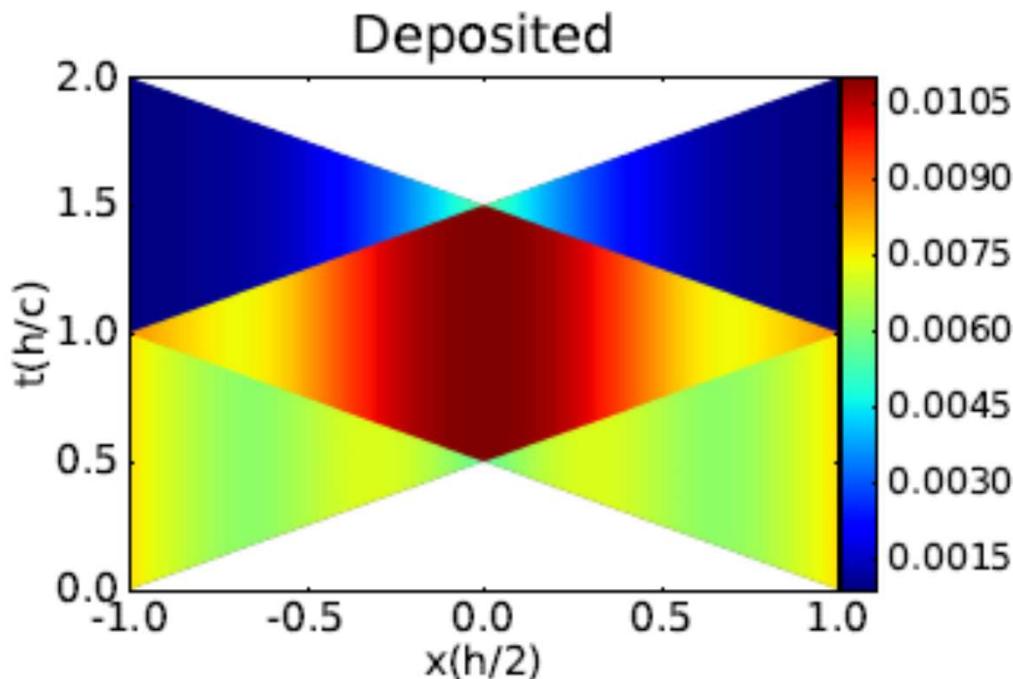

Figure 2: (color online) Deposited energy per unit time in the space-time across the depth,  $h$ , of the flat target. The time is measured in units of  $(h/c)$ , where  $c$  is the speed of light in the material of the target. The irradiation lasts for a period of  $\Delta t = h/c$  the time needed to cross the target. The irradiated energy during this time period is  $Q$  from one side, so it is  $2Q$  from both sides together.

The color code indicates the deposited energy per unit time and unit cross section (a.u.). The deposited length is  $\Delta x = c\Delta t$ . Note! The absorptivity in this case  $\alpha_K \neq \text{const}$ . For more details please see Appendix B.

## With nano antennas

Irradiation from both sides.

Ignition energy is:  $Q_i/m$   
 e.g. for DT target:  $Q_i/m = 27 \text{ kJ/g}$   
 → if we have  $Q = 100 \text{ J}$ , then  
 we can have a target mass:  
 $m_{DT} = Q / Q_i \text{ g} = 3.703 \text{ mg.}$

Then with  $m_{DT}$  and  $\rho_{DT}$  given  
 we get the DT-target's volume,  
 $V_{DT}$  and  $h_{DT} = 2.67 \text{ mm}$ .

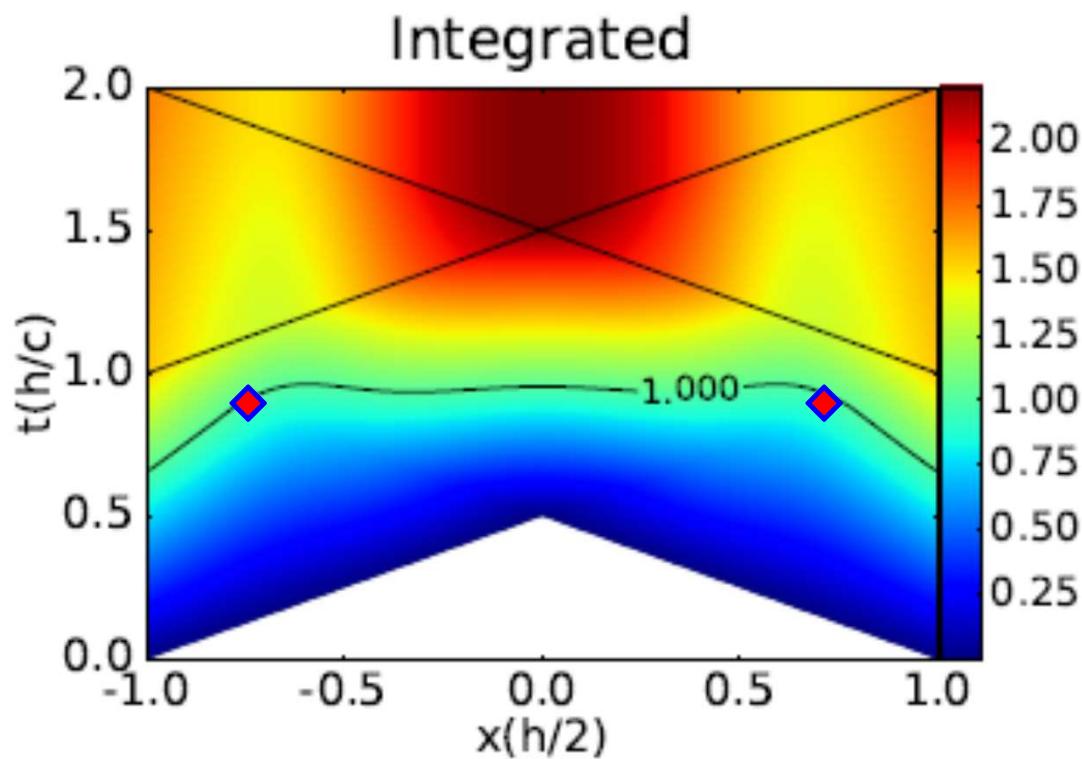

Figure 3: (color online) Integrated energy up to a given time in the space-time across the depth,  $h$ , of the flat target. The color code indicates the temperature,  $T$ , reached in a given space-time point, in units of the critical temperature, ( $T_c$ ). The contour line  $T = 1$ , indicates the critical temperature,  $T_c$  where the phase transition or the ignition in the target is reached. This contour line is almost at a constant time, indicating simultaneous whole volume transition or ignition. The irradiated energy,  $Q$  is chosen so that,  $1Q$  irradiation will achieve the critical temperature.

Csernai, L.P. [NAPLIFE}

**With nano  
antennas**

Ignition is reached at  
contour line  $Q = 1$ .
